## Smoothing Techniques

Lecturer: Jiaming Liang

November 12, 2024

Recall that the convex nonsmooth optimization complexity is

$$\mathcal{O}\left(\frac{M^2d_0^2}{\varepsilon^2}\right)$$
,

which is optimal for a black-box model, i.e., unstructured problems. However, if we know some structure of the problem, the complexity could be improved by taking advantage of this structural information. In this lecture, we explore the smoothable structure in nonsmooth optimization. The goal is to improve the complexity from  $\mathcal{O}(\varepsilon^{-2})$  to  $\mathcal{O}(\varepsilon^{-1})$ .

Consider

$$\min_{x \in \mathbb{R}^n} \{ \phi(x) := f(x) + h(x) + \theta(x) \}$$
 (1)

where f is convex, differentiable everywhere and L-smooth, h is closed, convex and simple, and  $\theta$  is convex (but not simple) and smoothable.

**Definition 1.** A function  $\theta$  is  $(C_1, C_2)$ -smoothable if there exist a scalar  $\mu > 0$  and a convex and differentiable function  $\theta_{\mu}$  such that

- $\theta_{\mu}(x) \leq \theta(x) \leq \theta_{\mu}(x) + C_2\mu$ ;
- $\nabla \theta_{\mu}$  is  $\frac{C_1}{\mu}$ -Lipschitz continuous.

For some  $\mu > 0$ , we consider an auxiliary problem

$$\min_{x \in \mathbb{R}^n} \{ \phi_{\mu}(x) := f(x) + h(x) + \theta_{\mu}(x) \}.$$

Let  $f_{\mu}(x) = f(x) + \theta_{\mu}(x)$ , then we know  $f_{\mu}$  is convex, differentiable everywhere, and  $\nabla f_{\mu}$  is  $\left(L + \frac{C_1}{\mu}\right)$ -Lipschitz continuous. Apply the ACG method with FISTA update to solve the auxiliary problem.

## Algorithm 1 FISTA

**Input:** Initial point  $x_0 \in \text{dom } h$ ,  $L_{\mu} = L + \frac{C_1}{\mu}$ , set  $y_0 = x_0$ ,  $A_0 = 0$ .

for  $k \geq 0$  do

Step 1. Compute

$$a_k = \frac{1 + \sqrt{1 + 4L_\mu A_k}}{2L_\mu}, \quad A_{k+1} = A_k + a_k, \quad \tilde{x}_k = \frac{A_k y_k + a_k x_k}{A_{k+1}}$$
 (2)

Step 2. Compute  $x_{k+1}$  and  $y_{k+1}$ 

$$y_{k+1} = \operatorname{argmin} \left\{ \ell_{f_{\mu}}(x; \tilde{x}_k) + h(x) + \frac{L_{\mu}}{2} ||x - \tilde{x}_k||^2 : x \in \mathbb{R}^n \right\},$$
$$x_{k+1} = \frac{A_{k+1}}{a_k} y_{k+1} - \frac{A_k}{a_k} y_k.$$

end for

**Theorem 1.** If  $\mu = \frac{\varepsilon}{2C_2}$ , then FISTA finds  $y_k$  such that  $\phi(y_k) - \phi_* \leq \varepsilon$  in at most

$$\mathcal{O}\left(\|x_0 - x_*\| \left(\sqrt{\frac{L}{\varepsilon}} + \frac{\sqrt{C_1 C_2}}{\varepsilon}\right)\right)$$

iterations.

*Proof.* In view of the first condition in Definition 1, we have for every  $x \in \text{dom } h$ ,

$$\phi_{\mu}(x) \le \phi(x) \le \phi_{\mu}(x) + C_2\mu.$$

Using this inequality and Theorem 1 of Lecture 7, we have

$$\begin{split} \phi(y_k) - \phi_* &= \phi(y_k) - \phi_{\mu}(y_k) + \phi_{\mu}(y_k) - \phi_{\mu}(x_*) + \phi_{\mu}(x_*) - \phi_* \\ &\leq C_2 \mu + \phi_{\mu}(y_k) - \phi_{\mu}(x_*) + 0 \\ &= \frac{\varepsilon}{2} + \frac{2L_{\mu} \|x_0 - x_*\|^2}{k^2} \\ &= \frac{\varepsilon}{2} + 2\left(L + \frac{C_1}{\mu}\right) \frac{\|x_0 - x_*\|^2}{k^2}, \end{split}$$

where the last identity is due to the definition of  $L_{\mu}$  in Algorithm 1. To find  $\varepsilon$ -solution, the complexity is

$$\mathcal{O}\left(\|x_0 - x_*\| \left(\sqrt{\frac{L}{\varepsilon}} + \frac{\sqrt{C_1 C_2}}{\varepsilon}\right)\right).$$

## Example

Consider the saddle point problem

$$\min_{x \in \mathbb{R}^n} \max_{y \in \mathbb{R}^m} f(x) + h(x) + \langle Ax, y \rangle - g(y)$$

or

$$\min_{x \in \mathbb{R}^n} f(x) + h(x) + \max_{y \in \mathbb{R}^m} \langle Ax, y \rangle - g(y),$$

where f is convex, differentiable everywhere and L-smooth, h is closed, convex and simple, g is a closed and convex function, and dom g is bounded.

Define

$$\theta(x) = \max_{y \in \mathbb{R}^m} \langle Ax, y \rangle - g(y) = g^*(Ax), \quad A \in \mathbb{R}^{m \times n}.$$

Then, the problem is in the form of (1) and  $\theta(x)$  is convex but not necessarily smooth.

**Lemma 1.** Assume  $\tilde{g}$  is a closed and  $\mu$ -strongly convex function, then

$$\tilde{\theta}(z) = (\tilde{g})^*(z) = \sup_{y \in \mathbb{R}^m} \langle z, y \rangle - \tilde{g}(y)$$

is convex and differentiable everywhere, and  $\nabla \tilde{\theta}(z) = y(z)$ . Moreover,  $\nabla \tilde{\theta}$  is  $\frac{1}{\mu}$ -Lipschitz continuous. Proof. See Lecture 5.

In our setup, we let

$$\tilde{g}(y) = g(y) + \frac{\mu}{2} ||y - y_0||$$

for some  $y_0 \in \text{dom } h$  and

$$\tilde{\theta}_{\mu}(z) = \sup_{y \in \mathbb{R}^m} \left\{ \langle z, y \rangle - g(y) - \frac{\mu}{2} ||y - y_0||^2 \right\}.$$

Then,

$$\nabla \tilde{\theta}_{\mu}(z) = y_{\mu}(z)$$

and it is  $\frac{1}{\mu}$ -Lipschitz continuous. Now let

$$\theta_{\mu}(x) = \tilde{\theta}_{\mu}(Ax),$$

then  $\theta_{\mu}$  is  $\frac{\|A\|^2}{\mu}$ -smooth. So we have  $C_1 = \|A\|^2$ . Moreover, we have for every  $x \in \text{dom } h$ ,

$$\theta_{\mu}(x) - \theta(x) \le \frac{\mu}{2} \max_{y \in \text{dom } g} ||y - y_0||^2,$$

so

$$C_2 = \frac{1}{2} \operatorname{Diam}(\operatorname{dom} g)^2.$$

Finally, applying Theorem 1, the complexity to find  $\varepsilon$ -solution is

$$\mathcal{O}\left(\|x_0 - x_*\| \left(\sqrt{\frac{L}{\varepsilon}} + \frac{\|A\| \operatorname{Diam}(\operatorname{dom} g)}{\varepsilon}\right)\right).$$
